METAGENOME SUMMARY

Dataset ssr15759Combo was uploaded on 10/02/2015 and contains 213,032 sequences totaling 63,696,506 basepairs with an average length of 299 bps. The piechart below breaks down the uploaded sequences into 3 distinct categories.

5,660 sequences (2.7%) failed to pass the QC pipeline. Of the sequences that passed QC, 285,372 sequences (134.0%) contain ribosomal RNA genes. 0 (0.0%) of the sequences that passed QC have no rRNA genes. 0 (0.0%) of the sequences that passed QC have no rRNA genes.

ANALYSIS FLOWCHART

5,660 sequences failed quality control. Of the 207,372 sequences (totaling 56,352,502 bps) that passed quality control, 285,372 (137.6%) produced a total of 3,415 identified ribosomal RNAs.

ANALYSIS STATISTICS

Upload: bp Count	63,696,506 bp
Upload: Sequences Count	213,032

Upload: Mean Sequence Length	299 ± 18 bp
Upload: Mean GC percent	53 ± 3 %
Post QC: bp Count	56,352,502 bp
Post QC: Sequences Count	207,372
Post QC: Mean Sequence Length	271 ± 82 bp
Post QC: Mean GC percent	53 ± 4 %
Processed: Predicted rRNA Features	4,069
Alignment: Identified rRNA Features	3,415

DRISEE [?]

Duplicate Read Inferred Sequencing Error Estimation (Keegan et al., PLoS Computational Biology, 2012)

DRISEE could not produce a profile, this is an Amplicon dataset.

DRISEE is a tool that utilizes artificial duplicate reads (ADRs) to provide a platform independent assessment of sequencing error in metagenomic (or genomic) sequencing data. DRISEE is designed to consider shotgun data. Currently, it is not appropriate for amplicon data.

Note that DRISEE is designed to examine sequencing error in raw whole genome shotgun sequence data. It assumes that adapter and/or barcode sequences have been removed, but that the sequence data have not been modified in any additional way. (e.g.) Assembly or merging, QC based triage or trimming will both reduce DRISEE's ability to provide an accurate assessment of error by removing error before it is analyzed.

KMER PROFILES [?] [HIDE](#)

Redraw the below plot using the following kmer-plot type:

kmer rank abundance

15-mer

The kmer abundance spectra are tools to summarize the redundancy (repetitiveness) of sequence datasets by counting the number of occurrences of 15 and 6 bp sequences.

The kmer spectrum plots the number of distinct N-bp sequences as a function of coverage level, placing low-coverage (rare) sequences at left and high-coverage,

repetitive sequences at right. The kmer rank abundance graph plots the kmer coverage as a function of abundance rank, with the most abundant sequences at left. The ranked kmer consumed graph shows the fraction of the dataset that is explained by the most abundant kmers, as a function of the number of kmers used.

NUCLEOTIDE POSITION HISTOGRAM [\[?\]](#) [HIDE](#)

These graphs show the fraction of base pairs of each type (A, C, G, T, or ambiguous base "N") at each position starting from the beginning of each read up to the first 302 base pairs. Amplicon datasets should show consensus sequences; shotgun datasets should have roughly equal proportions of basecalls.

[Download chart data](#)

SOURCE HITS DISTRIBUTION [?] HIDE

285,372 (134.0%) of reads had similarity to ribosomal RNA genes.

The graph below displays the number of features in this dataset that were annotated by the different databases below. These include protein databases, protein databases with functional hierarchy information, and ribosomal RNA databases. The bars representing annotated reads are colored by e-value range. Different databases have different numbers of hits, but can also have different types of annotation data.

[Download chart data](#)

TAXONOMIC HITS DISTRIBUTION HIDE

The pie charts below illustrate the distribution of taxonomic domains, phyla, and orders for the annotations. Each slice indicates the percentage of reads with predicted proteins and ribosomal RNA genes annotated to the indicated taxonomic level. This information is based on all the annotation source databases used by MG-RAST. An interactive [Krona](#) chart of the full taxonomy is also available. Click on a slice or legend to view all sequences annotated with the indicated taxonomic level in the analysis page.

RANK ABUNDANCE PLOT [HIDE](#)

Redraw the below plot using the following taxonomic level:

The plot below shows the phylum abundances ordered from the most abundant to least abundant. Only the top 50 most abundant are shown. The y-axis plots the abundances of annotations in each phylum on a log scale.

The rank abundance curve is a tool for visually representing taxonomic richness and evenness.

The image is currently dynamic. To be able to right-click/save the image, please click the static button

RAREFACTION CURVE [HIDE](#)

The plot below shows the rarefaction curve of annotated species richness. This curve is a plot of the total number of distinct species annotations as a function of the number of sequences sampled. On the left, a steep slope indicates that a large fraction of the species diversity remains to be discovered. If the curve becomes flatter to the right, a reasonable number of individuals is sampled: more intensive sampling is likely to yield only few additional species.

Sampling curves generally rise very quickly at first and then level off towards an asymptote as fewer new species are found per unit of individuals collected. These

rarefaction curves are calculated from the table of species abundance. The curves represent the average number of different species annotations for subsamples of the the complete dataset.

ALPHA DIVERSITY [\[?\]](#) [HIDE](#)

α -Diversity = 35.460 species

The above image shows the range of α -diversity values in project Sprague-ubiome-AprilB. The min, max, and mean values are shown, with the standard deviation ranges (σ and 2σ) in different shades. The α -diversity of this metagenome is shown in red.

Alpha diversity summarizes the diversity of organisms in a sample with a single number. The alpha diversity of annotated samples can be estimated from the distribution of the species-level annotations.

Annotated species richness is the number of distinct species annotations in the combined MG-RAST dataset. Shannon diversity is an abundance-weighted average of the logarithm of the relative abundances of annotated species. The species-level annotations are from all the annotation source databases used by MG-RAST.

[DOWNLOAD THIS METAGENOME](#)

We provide download capabilities for the submitted sequences, metadata, and all files with results that are produced in the process of MG-RAST analysis on the [download page for this metagenome](#). This includes fasta files with annotations using the [M5NR](#).

We also provide access to the blat alignment summaries underlying our sequence analysis work on the [download page](#).

Please note: The graphs on this page allow downloading the underlying information as tables. The search results and most of the pie-charts allow selecting the fraction of sequences in an element to work with in the [workbench](#) feature on the [analysis page](#).

ANALYZE THIS METAGENOME

The [analysis page](#) provides access to analysis and comparative tools including tables, bar charts, trees, principle coordinate analysis, heatmaps and various exports (including FASTA and QIIME). The [workbench](#) feature allows sub-selections of data to be used e.g. select all E. coli reads and then display the functional categories present just in E. coli reads across multiple data sets.

SEARCH THIS METAGENOME

Below searches return all predicted functions or organisms that contain the input text.
